Appendix B: Relationship of Capital Account Gini to the U.S. Political Economy, and Comparison of Current Account Gini with Capital Account Gini

Changes in the US’s national accounts are associated with changes in the Gini coefficients of global capital flows. Indeed, these are correlated at very high levels: the US’s current account imbalance is correlated with the global current account Gini coefficient for the ten largest imbalances at 0.88; the equivalent correlation between the US’s capital account imbalance and the global capital account Gini coefficient is 0.75, with the difference due to accounting discrepancies (and the IMF’s somewhat unique accounting device). When we expand the search to the top 20 largest imbalances the correlation with the US is still fairly strong: 0.69. Thus, American imbalances drive global imbalances.

Figure 1: The Relationship Between the U.S. Capital Account Balance and the Global Capital Account Gini Coefficient (top 20 imbalances), 1975–2015. The correlation is roughly 0.69.

If US capital account (or, in IMF terminology, financial account) imbalances drive global KA inequality, why not use the size of the US capital account balance or its size relative to the absolute value of capital account balances globally as our primary outcome measure? We choose to use KA Gini rather than just the U.S. cap-

ital account for two reasons. First, following the presentation of previous versions of this paper we were strongly encouraged to use a measure that could capture the role of other major economies; the KA Gini does this by including the size of the largest 10 capital account surpluses and therefore is able to capture a more nuanced state of the world.

Second, we also want to be able to account for global developments during the periods when US imbalances are low, particularly if other major economies are absorbing the flows that the US would be. While we do not observe this in the data, it could be possible that the US has a small capital account surplus but that globally imbalances are large and concentrated. Therefore, our measure is more informative than just the size of the US capital account imbalance, even scaled by the absolute size of global capital account imbalances. It is also flexible to the possibility that other countries will become more central to the global financial system over time, and therefore will increasingly be more consequential to patterns of abnormal capital events (bonanzas and banking crises). Because the US KA and KA Gini are so highly correlated (see above), it is not possible to adjudicate a question of which measure is better by including both variables on the right hand side of the same equation. Doing so would insert considerable inconsistency in our estimations. However, to assure readers that our choice to use KA Gini is not driven by forum shopping for key variables, we include below two tables that shows our results for our fully specified models (models 5 & 6 and models 11 & 12) are robust to substituting US KA balance and US KA/Absolute Value of Global KA balance for KA GINI. (Note that for Crisis models, the coefficient estimate for US KA/WORLD slips just over conventional measures of statistical significance, but broadly, our results hold)

Table 5: Determinants of banking crises. Once again, the global effects dominate the local effects (except for economic growth rate.)

Appendix C: Constructing Regional Contagion Measures

To construct the regional bonanza measure, we do the following. First, we generate a count of all bonanzas within a region for a given year. Next, for each country-year observation, we subtract the observation's value for *Bonanza*. To create a ratio (since regions are not of equal size), we divide the number of adjusted regional bonanzas by the number of countries in the region. Next, we run several models of *Adjusted Regional Bonanzas* using *Capital Account Inequality* as the explanatory variable (poisson, random effects cross sectional time series, standard regression with country fixed effects, standard regression with region fixed effects). We extract residuals from these models and inspect their normal quantile plots. We choose, based on the normality of residual distribution, to use the residuals generated by the standard regression with country fixed effects. Code and plots are below:

```
** poisson
xtpoisson adjregionbonanzaratio fa_gini_10, fe
predict yhat_adjregionbonanzaratio
gen res_regionbonanzaratio=adjregionbonanzaratio-yhat_adjregionbonanzaratio
qnorm res_regionbonanzaratio

** random effects cross sectional time series
xtreg adjregionbonanzaratio fa_gini_10, re
predict regbon_hat_ratio_re
gen regbon_ratio_re_res=adjregionbonanzaratio-regbon_hat_ratio_re
qnorm regbon_ratio_re_res

** standard regression with country fixed effects
regress adjregionbonanzaratio fa_gini_10 i.iso3n
predict regionbonanzaka_ratio_res,res
qnorm regionbonanzaka_ratio_res

** standard regression with region fixed effects
regress adjregionbonanzaratio ka_gini_10 i.region
```

```

predict regionbonanza_ratio_res,res
qnorm regionbonanza_ratio_re

** standard regression with country fixed effects is the best
egen stdregionbonanzaka_ratio_res=std(regionbonanzaka_ratio_res)

** With CA Gini for CA Models
reg adjregionbonanzaratio ca_gini_10 i.iso3n
predict regbon_ratio_fe_res, res
qnorm regbon_ratio_fe_res
egen stdres_regionbonanza_fe=std(regbon_ratio_fe_res)

```

The regional crisis measure was constructed in similar fashion.

A reviewer suggested we consider whether the dynamics we find in our empirical analysis hold during the “global savings glut” of the 2000s. Constraining our sample to the aughts is difficult because of issues of power; truncating the sample so much simply reduces our ability to estimate efficient models. However, we are able to run analysis from 1999 onward for our global and regional models in random effects specifications. Since fixed effects models exclude any country that did not experience a bonanza or a banking crisis during the sample time period, constraining our analysis to one decade makes these model specifications untenable. Additionally, we run into modeling issues with our fully specified models due to additional missing data that make these models particularly unreliable for so short a time period. Below, we report results of these models. However, while the statistical significance of KA GINI is robust to the restricted time period, we do urge caution in interpreting these models since the time frame is so small.
